Why Inductive Position Sensors?

- **Automotive Electronics must work in extreme weather conditions, e.g. dust, humidity, vibration and wide temp range -40°C to $+90^{\circ}\text{C}$**
- **Non-contact type & low cost solutions needed**
- **Resistive/Capacitive Sensors will be unsuitable**
- **Hall Sensors with Magnets were usually used**
- **They have some problems, e.g. magnet fixing with adhesive/glue, B(remanence) changes with temp, compensation needed, not so cheap etc.**

Inductive Position Sensors

Figure: Inductive Position Sensor

- Planar coils are fabricated directly on the PCB
- Double layers coils are often needed
- Other shapes e.g. rectangular, trapezoidal, circular, elliptical are also possible

How does it work?

Figure: Inductive Position Sensor

- **Activator** is a very thin Rhombus shape Cu-plate
- **Slides horizontally over the coils** (fixed vertical gap)
- **Multiple coils' inductances are affected due to Cu-Activator** (eddy current's effect)

Modeling of Inductive Pos. Sensor

$$V_p = I_p R_p + L_p \cdot dI_p / dt - M \cdot dI_s / dt ,$$
$$M \cdot dI_p / dt = I_s (R_s + Z_L) + L_s \cdot dI_s / dt$$

$$V_p / V_s = I_s / I_p = N_p / N_s = a ,$$
$$M = K_{coupl} \sqrt{L_p L_s} , a = \sqrt{L_p / L_s}$$

$$I_s = a I_p , \quad V_p = (L_p - aM) dI_p / dt$$

$$aM = K_{coupl} L_p , \quad V_p = (1 - K_{coupl}) L_p dI_p / dt$$

- Inductive position sensor can be viewed as a leaky (*air core*) and loosely coupled transformer
- Planar coils behave like a primary and activator is like a shorted secondary winding with one turn.

Simulations Results (single & double layer)

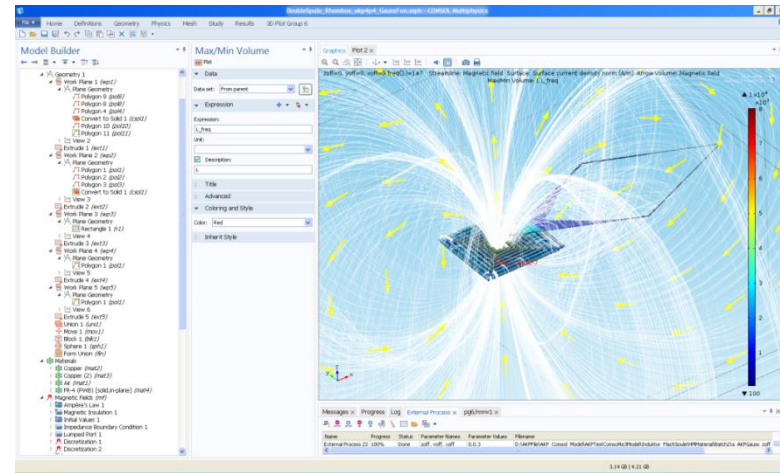

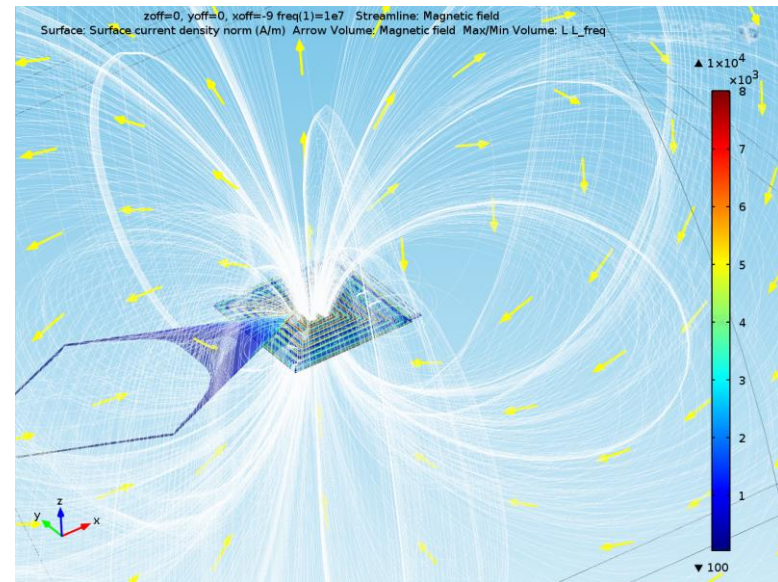

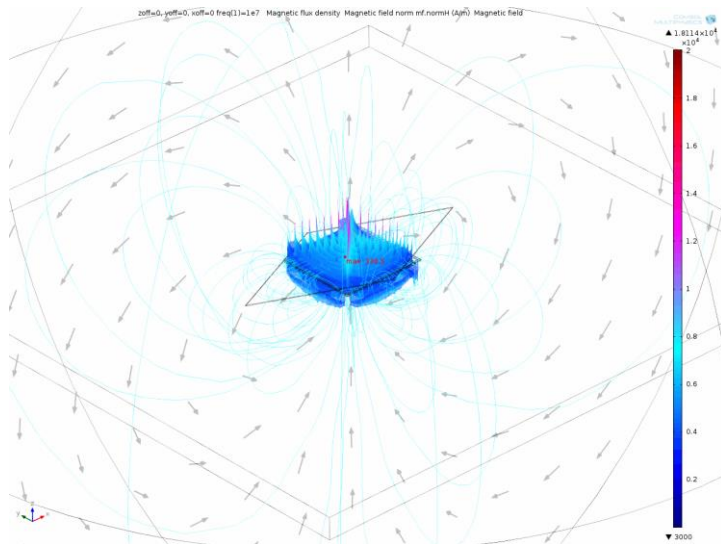

Figure: Cu-activator's X-off position (mm) vs. Inductance (nH) graph for a single (left-bottom) & double layer (right-bottom curve) planar coil.

Simulations Results (2-layer Coils)

Conclusion

- ✓ Inductive position sensor was modeled as a leaky/loosely coupled (*air core*) transformer with a shorted secondary winding (one turn) and operated at MHz frequency.
- ✓ Multiple coils' inductances are influenced (reduced) by the Cu-Activator element
- ✓ Xoff-position vs. Inductance curve (single/double layer) of planar coil looks like an inverted Gaussian function
- ✓ Sensor's sensitivity is dependent on operating frequency and shape, size, location (both horizontal & vertical) of the activator element over the coil
- ✓ The results have been implemented in the development of an automatic gear shifter module of a leading German car

Thank you for your Attention!
